CRICKSTATS

Salesforce-Based Cricket Player Statistics Management System

Project Documentation

Item	Details
Project Platform	Salesforce Developer Edition
Application	CRICKSTATS
Main Objects	Player, Match Performance
Main Automation	Screen Flow and Home Page Flow
Project Type	Salesforce CRM / Low-Code Application

1. Project Overview

CRICKSTATS is a Salesforce application created to manage cricket player information and match-performance statistics. The application stores player records, match performance records, calculates summary statistics, and provides a simple flow-based interface for viewing players by team.

1.1 Purpose

The purpose of the project is to demonstrate how Salesforce objects, custom fields, relationships, roll-up summary fields, Lightning Apps, and Flow Builder can be combined to build a practical cricket statistics management application.

1.2 Key Features

- Player information management.
- Match Performance information management.
- Team-based player selection.
- Custom cricket statistics such as runs, fours, sixes, wickets and overs.
- Roll-up summary statistics on the Player object.
- Screen Flow for selecting a team and displaying matching players.
- Data Table used to display player results.
- CRICKSTATS Lightning App with Players, Match Performances, Reports and Dashboards.

2. Salesforce Developer Account Creation

Activity 1: Creating Developer Account

A Salesforce Developer Edition environment was created and used as the development environment for the CRICKSTATS project. The developer environment provides access to Salesforce Setup, Object Manager, App Manager, Flow Builder and other configuration tools.

Activity 2: Account Activation

The developer account was activated and used to access the Salesforce setup environment and create the application components required for CRICKSTATS.

3. Object Creation

Activity 1: Player Object

A custom Player object was created to store individual cricket player information. The object acts as the parent/master record for the match-performance information.

Activity 2: Match Performance Object

A custom Match Performance object was created to store statistics for individual player performances in matches.

Object	Purpose
Player	Stores player identity, team and calculated career/statistical summaries.
Match Performance	Stores statistics for a player's individual match

	performance.

4. Tabs

Activity 1: Custom Tabs Creation

Custom tabs were created so that the Player and Match Performance objects could be accessed directly from the Salesforce application navigation.

- Players tab – used to create, view and manage player records.
- Match Performances tab – used to create and view match-performance records.

5. The Lightning App

Activity 1: Create a Lightning App

A Lightning App named CRICKSTATS was created using App Manager. The application provides a single navigation area for the main cricket-statistics components.

App Component	Use
Players	Manage player records.
Match Performances	Manage match statistics.
Reports	View structured Salesforce reports.
Dashboards	View graphical/summary information.

6. Fields & Relationships

Activity 1: Create Custom Fields for Player Object

Custom fields were added to the Player object to store cricket-related information and calculated values. The project includes fields such as Team and statistical summary fields including Matches Played, Number of 50's, Number of 100's, Total Runs, Total 4's, Total 6's, Total Overs and Total Wickets. An average score field was also used in the player display.

Activity 2: Create Custom Fields for Match Performance Object

The Match Performance object contains fields needed to record a player's performance in a particular match.

Field / Information	Purpose
Match Performance Name	Identifies the performance record.
Player	Associates the performance with a player.
Runs / Score	Records runs scored by the player.
Fours	Records the number of fours.
Sixes	Records the number of sixes.
Balls Faced	Records balls faced by the player.
Overs Bowled	Records overs bowled.
Wickets Taken	Records wickets taken.

Runs Conceded	Records runs conceded while bowling.
Maiden Overs	Records maiden overs.
Stumping	Records stumpings.
Catches	Records catches.
Player of the Match	Records whether the player received the award.
Match Result	Stores the match result.

6.1 Relationship Between Objects

The Player and Match Performance objects are connected so that match-performance records can be associated with the relevant player. This relationship allows Salesforce to use the child Match Performance records when calculating roll-up statistics on the Player record.

7. Roll-up Summary

Activity 1: Create Roll-up Summary for Player Object

Roll-up summary fields were configured on the Player object to calculate aggregate statistics from related Match Performance records. This allows the Player record to show summary information without manually entering every total.

- Matches Played – counts related Match Performance records.
- Number of 50's – counts performances meeting the required 50-run condition.
- Number of 100's – counts performances meeting the required 100-run condition.
- Total Runs – summarizes runs from related performances.
- Total 4's – summarizes fours.
- Total 6's – summarizes sixes.
- Total Overs – summarizes overs bowled where configured.
- Total Wickets – summarizes wickets taken where configured.

If a player has no related Match Performance records, the roll-up values naturally remain zero. After match-performance records are entered for that player, the related summary values can update according to the configured roll-up criteria.

8. Flows

Activity 1: Screen Flow

A Screen Flow named Player Flow was created in Flow Builder. The flow allows the user to select a team and view the players belonging to that team.

1. Create/open the Player Flow in Flow Builder.
2. Use a Team picklist on the screen.
3. Use the Team choice / choice-set configuration to provide the available team values.
4. Use Get Records to retrieve Player records.
5. Filter the Player records using the selected Team value.
6. Store the matching Player records in a record collection.
7. Display the results using a Data Table.

8. Save the flow as a new version and activate the required version.

8.1 Screen Components Used

Component / Resource	Purpose
Team Picklist	Allows the user to choose a team such as RCB.
Team Choice / Choice Set	Provides team choices for the picklist.
Get Records – Players	Retrieves Player records based on the selected team.
Players from Players	Record collection containing the retrieved players.
Data Table	Displays the player results in columns.
Dynamic Variable	Stores the selected Team value for use in filtering.

During testing, the flow was configured so that selecting RCB returned the created player record, including Virat Kohli. The flow therefore demonstrated that the team selection and player filtering were working.

Activity 2: Flow on Home Page

The project also includes the Flow on Home Page activity. The purpose is to make the flow accessible from the Salesforce home experience so users can interact with the player-selection feature without navigating deeply through Setup.

9. Testing and Results

The CRICKSTATS application was tested by creating player records and entering match-performance information. The Player page displayed the player and the configured statistical fields. The Screen Flow was tested by selecting a team and confirming that the corresponding player appeared in the results table.

Test	Expected Result	Observed Result
Create Player	Player record should be created.	Player record created successfully.
Select Team in Flow	Players belonging to selected team should appear.	Player result displayed.
No Match Performance	Roll-up values should remain zero.	Values displayed as 0.
Add Match Performance	Related Player statistics should update according to configuration.	Statistics can be reflected through configured roll-up fields.
Open CRICKSTATS App	Main Salesforce objects should be accessible.	Players, Match Performances, Reports and Dashboard areas available.

10. Conclusion

CRICKSTATS demonstrates the use of Salesforce declarative development to build a cricket statistics management application. The project combines custom objects, fields, object relationships, roll-up

summaries, Lightning App configuration and Flow Builder. The application provides a structured way to store player and match information and offers a simple screen-based method for finding players by team.

11. Future Enhancements

- Add more advanced reports and dashboards for team and player comparison.
- Add validation rules for cricket statistics to reduce incorrect entries.
- Add more automated calculations such as batting average and strike rate.
- Add filters for season, match type and date.
- Improve the home page with additional summary components.
- Add more flow screens for entering or reviewing match performance.

12. Technologies and Salesforce Features Used

Technology / Feature	Role in Project
Salesforce Developer Edition	Development and testing environment.
Custom Objects	Player and Match Performance data storage.
Custom Fields	Cricket-specific data capture.
Relationships	Connect Player with Match Performance.
Roll-up Summary	Calculate aggregate player statistics.
Lightning App	Provide the CRICKSTATS application interface.
Flow Builder	Create the interactive Player Flow.
Screen Flow	Allow team selection and player display.
Get Records	Retrieve player records.
Data Table	Display retrieved player information.
